In the years following the Fukushima Dai-ichi Nuclear Power Plant (FDNPP) accident in 2011, monitoring of less radiologically relevant radionuclides has received limited attention. This is the case of  $^{90}\text{Sr}$ ,  $^{129}\text{I}$  and actinides ( $^{236}\text{U}$  and Pu-isotopes). Their monitoring is however important because: i) they can be proxies for other radionuclides with radiological interest; and/or ii) they are suitable as geochemical tracers providing valuable information about hydrological, atmospheric, and geochemical processes. Additionally, two years after the accident,  $^{90}\text{Sr}$  was still a major contaminant in waters accumulated within the nuclear facility and storage tanks.

In 2013 and 2014, three cruises took place in the coast off Japan, with the aim to re-evaluate the concentrations and the distribution of artificial radionuclides from FDNPP and identify the current potential sources of these isotopes, with particular emphasis to  $^{90}\text{Sr}$ .

Here we present results of  $^{90}\text{Sr}$ ,  $^{129}\text{I}$ ,  $^{236}\text{U}$  and Pu-isotopes from May 2013, May 2014 and October 2014 onboard R/V Daisan Kaiyo Maru and R/V Shinsei Maru. Surface concentrations of  $^{90}\text{Sr}$  and  $^{129}\text{I}$  up to  $8.9 \pm 0.4 \text{ Bq} \cdot \text{m}^{-3}$  [1] and  $780 \pm 15 \times 10^7 \text{ at} \cdot \text{kg}^{-1}$ , respectively, suggest ongoing releases of these radionuclides from the FDNPP. Potential releases of  $^{236}\text{U}$  and Pu-isotopes remain under discussion. The evolution of atomic and/or activity ratios of  $^{137}\text{Cs}/^{90}\text{Sr}$ ,  $^{129}\text{I}/^{137}\text{Cs}$ ,  $^{129}\text{I}/^{90}\text{Sr}$  with time corroborate the ongoing releases of radionuclides to the coast off Japan.

Upper boundary estimates of  $^{90}\text{Sr}$  and  $^{129}\text{I}$  releases during the years following the FDNPP accident are minor compared to the total amounts released in 2011. Yet this study indicates that a continuous surveillance of artificial radionuclides to the Pacific Ocean is still required.
